Bias Exploration

To explore potential areas of bias, we will endeavor to trace class imbalance on the target feature of "oci desc."

```
68.0 % of streets are in good condition 27.0 % of streets are in fair condition 5.0 % of streets are in poor condition
```

Considerably more than half of the streets are in good condition. A little less than a third are in fair condition. Only 5% are in poor condition.

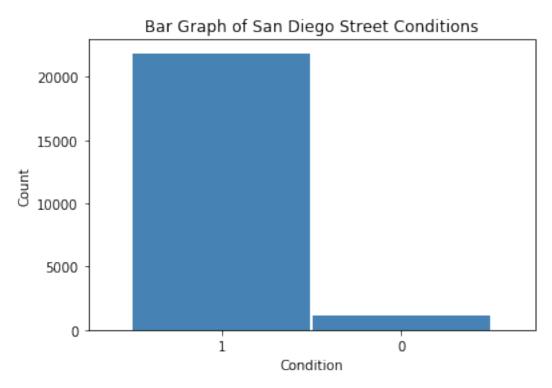

```
[22]: Good 15758
Fair 6105
Poor 1142
Name: oci_desc, dtype: int64
```

Whereas a method can be used to classify street conditions into multiple classes, it is easier to re-classify streets in "fair" and "good" condition into one category in comparison with the poor class. This, in turn, becomes a binary classification problem. Thus, there are now 21,863 streets in good condition and 1,142 in poor condition (only 5% of all streets). This presents a definitive example of class imbalance.

```
[23]: 1 21863
0 1142
Name: oci_cat, dtype: int64
```

```
plt.xlabel('Condition')
plt.ylabel('Count')
plt.show()
cond
```

```

Boxplot Distribution

```
The first quartile is 66.3. The third quartile is 87.3. The IQR is 21.0. The mean is 74.79. The standard deviation is 16.78. The median is 79.06.
```

Correlation Matrix

```
[33]: # assign correlation function to new variable
corr = df.corr()
matrix = np.triu(corr) # for triangular matrix
```

Multicollinearity

Let us narrow our focus by removing highly correlated predictors and passing the rest into a new dataframe.

These are the columns prescribed to be dropped: ['area_sq_ft', 'oci_wt', 'length', 'width', 'paving_miles']

Pre-Processing

Feature Engineering

The residential, collector, major, prime, local, and alley functional classes are converted to dummy variables.

The AC Improved, PCC Jointed Concrete, AC Unimproved, and UnSurfaced pavement classes are converted to dummy variables.

The current status of the job (i.e., post construction, design, bid/award, construction, and planning) is also converted to dummy variables.

The start date is subtracted from the end date and converted to number of days as one column.

Dropping Non-Useful/Re-classed Columns

Columns with explicit titles (i.e., names) and non-convertible/non-meaningful strings are dropped. Redundant columns (columns that have been cast to dummy variables) have also been dropped in conjunction with the index column which serves no purpose for this experiment.

The original dataframe is copied into a new dataframe df1 in order to continue the final steps in the preprocessing endeavor. This is to avoid any mis-steps or adverse/unintended effects on the original dataframe.

```
[40]: # create new dataframe for final pre-processing steps
df1 = df.copy()
```

The dataframe can now be prepared as a flat .csv file if so desired.

```
[41]: # output to csv file as backup
# df.to_csv('sd_roads_dataframe.csv')
```

Handling Class Imbalance

Multiple methods for balancing a dataset exist like "undersampling the majority classes" (Fregly & Barth, 2021, p. 178). To account for the large gap (95%) of mis-classed data on the "poor" condition class, "oversampling the minority class up to the majority class" (p. 179) is commenced. However, such endeavor cannot proceed in good faith without the unsupervised dimensionality reduction technique of Principal Component Analysis (PCA), which is carried out "to compact the dataset and eliminate irrelevant Features" (Naseriparsa & Kashani, 2014, p. 33). In this case, a new dataframe is reduced down into the first two principal components since the largest percent variance explained exists therein.

```
[42]: # the first two principal components are used
pca = PCA(n_components=2, random_state=777)
data_2d = pd.DataFrame(pca.fit_transform(df1.iloc[:,0:9]))
```

The dataframe is prepared for scatterplot analysis as follows.

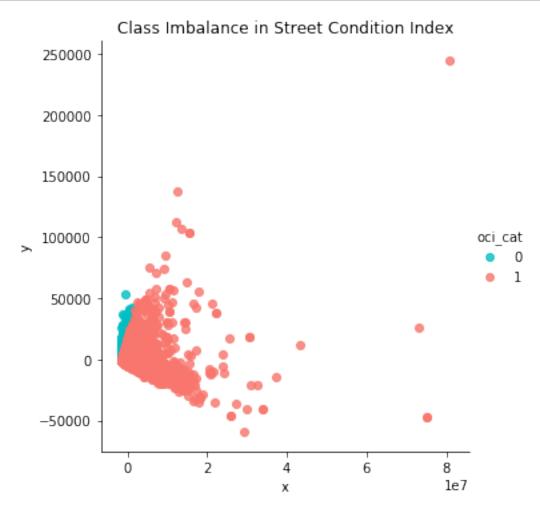

```
[43]: data_2d= pd.concat([data_2d, df1['oci_cat']], axis=1)
data_2d.columns = ['x', 'y', 'oci_cat']; data_2d
```

```
[43]:
                                     oci_cat
              -565,511.24 14,903.90
      0
                                            0
               438,106.89 -5,292.13
                                            1
      1
      2
              -290,656.73 3,118.86
                                            1
      3
              -123,365.87 1,734.80
                                            1
      4
              -958,462.83 11,356.77
      22993 -1,120,094.45 -2,138.79
                                            1
      22994 1,469,689.03 -5,161.03
                                            1
```

```
22995 1,321,569.31 -6,995.59 1
22996 -846,170.55 -2,671.76 1
22997 -932,156.28 -1,420.73 1
```

[22998 rows x 3 columns]

```
[44]: sns.lmplot('x','y', data_2d,fit_reg=False,hue='oci_cat', palette=['#00BFC4','#F8766D'])
plt.title('Class Imbalance in Street Condition Index'); plt.show()
```

The dataset is oversampled into a new dataframe df2.

The adaptive synthetic sampling approach is leveraged in conjunction with the Synthetic Minority Oversampling (SMOTE) technique to "balance the class distribution and increase the variety of sample domain" (p. 33). This allows for the minority class to be more closely matched (up-sampled) to the majority class for an approximately even 50/50 weight distribution.

```
[45]: ada = ADASYN(random_state=777)
X_resampled, y_resampled = ada.fit_resample(df1.iloc[:,0:13], df1['oci_cat'])

[46]: df2 = pd.concat([pd.DataFrame(X_resampled), pd.DataFrame(y_resampled)], axis=1)
df2.columns = df1.columns
```

The classes are re-balanced in a new dataframe using oversampling:

```
[47]: # rebalanced classes in new df
      df2['oci_cat'].value_counts()
      zero_count = df2['oci_cat'].value_counts()[0]
      one_count = df2['oci_cat'].value_counts()[1]
      zero_plus_one = zero_count + one_count
      print('Poor Condition Size:', zero_count)
      print('Good Condition Size:', one count)
      print('Percent in Poor Condition:', round(zero_count/zero_plus_one,2))
      print('Percent in Good Condition:', round(one count/zero plus one,2))
     Poor Condition Size: 21844
     Good Condition Size: 21858
     Percent in Poor Condition: 0.5
     Percent in Good Condition: 0.5
     Train-Test-Validation Split
[48]: #Divide train set by .7, test set by .15, and valid set .15
      size_train = 30592
      size test = 6555
      size_valid = 6555
      size_total = size_test + size_valid + size_train
      train, test = train_test_split(df2, train_size = size_train,
                                    random_state = 777)
      valid, test = train_test_split(df2, train_size = size_test,
                                    random_state = 777)
      print('training size:', size_train)
      print('validation size:', size_valid)
      print('test size:', size_test)
      print('training percentage:', round(size_train/(size_total),2))
      print('validation percentage:', round(size_valid/(size_total),2))
      print('test percentage:', round(size_test/(size_total),2))
     training size: 30592
     validation size: 6555
     test size: 6555
     training percentage: 0.7
     validation percentage: 0.15
     test percentage: 0.15
[49]: X_var = list(df2.columns)
      target = 'oci_cat'
      X_var.remove(target)
      X_train = train[X_var]
      y_train = train[target]
      X_test = test[X_var]
      y_test = test[target]
      X_valid = valid[X_var]
```

y_valid = valid[target]
